

Dear Kubescape Maintainers and Selection Committee,

I am excited to apply for the **Kubescape eBPF/gVisor project**. This marks my return to active open-source contribution nearly four years after Google Summer of Code and following a break from full-time work. Although LFX allowed applications to three projects, **Kubescape is the only one I applied to** - a deliberate choice because the problem space closely matches the security systems I have spent the past several years building.

My experience spans **kernel-level agents, eBPF runtime tracing, process lineage, network interception, sensitive-data egress detection, and detection pipelines**. What interests me most, however, is not simply collecting runtime telemetry, but converting it into useful security context: understanding what happened, establishing relationships and causality, and surfacing detections or insights that users can actually act on.

That is the perspective I would bring to Kubescape. I approach runtime security from both an **agent and product perspective**: what can we observe reliably, what can we infer from those signals, and what valuable security capabilities become possible once that visibility exists? As workloads increasingly include autonomous and agentic activity, reconstructing endpoint behavior and turning it into meaningful security context becomes even more important.

Kubescape is especially compelling because an open-source runtime security platform creates room not only to implement features, but to explore new detections, correlations, and product use cases openly. I believe my combination of **security engineering, product experience, low-level systems work, and prior open-source exposure** would allow me to contribute meaningfully both to the implementation and to identifying where the technology can go next.

I am returning to open source deliberately, and Kubescape is where I would like to invest that effort.

Thank you for considering my application.

Yash Gupta
